FOREWORDS

Dr. Lourival Carmo Monaco

Fundecitrus President and citrus grower

The month of May has definitely been incorporated into the citrus production chain schedule. The Crop Forecast Survey (PES) strategy, implemented by request from the Fundecitrus Management Board, confirms citrus growers' expectations of applying concepts of good practices in citriculture. The initiative, now in its fifth round, has evolved. The credibility it has gained shows its importance to the future, towards continuous improvement and acknowledgement by the market.

Knowing the profile of our citriculture in different climatic, historical and social conditions sets the context to comprehensively bring sustainability concepts into harmony with economic, social and environmental variables.

This crop season once again has highlighted the biennial behavior of this perennial crop. Production, quite similar to that of 2017-2018 and well above last year's, confirms this pattern. The challenge in this area is to work on research and development in order to define how best management conditions can contribute to a lower biennial variability.

In the 2019-2020 crop season, results have shown a positive trend in our citriculture with the adoption of the commandments to manage greening, influencing its expansion dynamics, with decreased abandoned groves, a slight rise in new plantings and increased yield.

PES has become the source of fundamental knowledge to the process of intensifying recognized measures toward sustainability. Plenty of information available should be studied and interpreted in the analysis of solutions for each type of farm. The citrus production chain will demand ever more integration of its links in order to maintain its competitiveness in meeting market needs.

Antonio Juliano Ayres

Fundecitrus General Manager

The 2019-2020 crop forecast and tree inventory for São Paulo and West-Southwest Minas Gerais, in their fifth consecutive year, bring precise and reliable information to citrus growers. The record yield presented confirms the leadership trend of our citriculture, even amid adversities caused by pests and diseases. Climatic factors largely influenced the increased yield. After the drought from April to July, when rainfall was nearly a third of the average amount for that time period [1981-2010], August rains in the Central, South and Southwest sectors, and September rains in the North and Northwest sectors moved flowering to the harvest. During post-bloom, mild temperatures in addition to summer rains that kept the water available favored the setting of fruits and fruitlets, which resulted in a highly productive crop. However, it is necessary to remark that citriculture in São Paulo started a revolution twenty years ago. Climate is a conjunctural issue and the high yield must be assessed in a structural manner. Yield results from a series of factors such as protected nurseries, soil tillage and cultural practices especially regarding nutrition and irrigation, evaluation of the best planting regions, grove density, proper combination of rootstock and scion and control of CVC (citrus variegated chlorosis) and greening. PES, developed with the support from citrus growers and credible institutions, contributes to the evolution and revolution in citriculture by ensuring the democratization of information to the whole sector, with transparency and precision.

Marcos Fava Neves

PES Political-Institutional and Methodological Coordinator, part-time Full Professor at FEA-RP/USP and other organizations

I am extremely pleased to participate once again in the PES announcement event, in its fifth round in this year of 2019. Our baggage of knowledge has evolved along these five years, ensuring greater precision to the methodology and the survey. The result of all this is an accurate image of São Paulo and West-Southwest Minas Gerais citrus belt, which provides relevant contributions to all production chain agents. Such collective efforts are made by Fundecitrus, the main organization in the sector, and its loyal research partners, namely Markestrat, FEA-RP/USP and FCAV/Unesp, aiming at democratizing the access to information with transparency in the sector. Undoubtedly, this initiative inspires other agribusiness production chains in Brazil and abroad. On our part, in addition to the political and institutional coordination, I would like to also highlight the efforts we made towards international visibility of PES, in our participation in the Citrus Summit this year, in Port Elizabeth (South Africa) and by launching the book "Orange Juice Chain - Past, Present and Future" in that same town, with wide publicity both physical and digital. Congratulations to all involved and may we have excellent results this crop season, "creating, capturing and sharing value" and "accomplishing the winning mission" of Brazilian citriculture.

Vinícius Gustavo Trombin

Executive Coordinator of PES and partner at Markestrat

Upon the 2019-2020 crop forecast announcement, citrus growers already worry about the next season. Although thinking of times ahead is necessary, understanding the present is equally important. We hope the information published in this fifth round of PES helps all citrus growers understand the current status of groves and develop studies and comparisons between their data and those for the sector. The analysis of indexes such as average productivity in the region their farms are located shows whether their performance is above or below average. This self-assessment should not be an end in itself but must be incorporated as a continuous learning and improvement process. Incidentally, all those willing to reach exceptional results in their work should constantly seek the enhancement of what they do. This is the philosophy we have adopted at PES since its beginning and have therefore improved its methodology. It is worth mentioning the regression model we introduced last season, through which we were able to estimate still in May the weight of oranges at harvest, with an error of only 1%. This season we are testing two new methodologies that should bring even more precision to the surveys. The first one is related to surveying fruit drop by the use of collecting nets and the second is associated with monitoring the weight of oranges throughout the crop season with a tool we developed to make fruit sampling random. Now, back to the initial question: for obvious reasons we cannot at this time respond to the concerns of citrus growers regarding the next crop season, but we can assure the efforts of the whole PES team are directed to our doing our best work in a serious and ethical way and keeping data confidential. This is our duty to citrus growers, who not by chance are scoring big in terms of productivity this crop season.

José Carlos Barbosa

Methodological Analyst at PES and (Voluntary) Full Professor at FCAV/Unesp

In the fifth year of the Crop Forecast Survey carried out by Fundecitrus, new models to estimate fruit weight have been used. New methodologies to monitor fruit weight and drop have been developed and are under implementation. PES team remains consolidated and is increasingly more capable of carrying out the crop forecast with every passing year. The productive sector's trust on the crop estimate carried out by Fundecitrus is further developed each year.

ACKNOWLEDGEMENTS

We start by thanking citrus growers and the orange juice companies Citrosuco, Cutrale and Louis Dreyfus Company, which enabled and funded this survey and voluntarily made their farms available so that we could gather reliable and updated information for the benefit of all.

We also thank the São Paulo State department of agriculture and supply, which through CDA-SP (São Paulo State animal and plant health protection agency) provided information on the number of nursery citrus plants marketed under the permit to transit plants in 2018.

We acknowledge the important support from the Technical Committee through permanent exchange of field experiences and joint efforts to face all challenges and encourage the refinement of the methodology.

We thank those who collaborate to Fundecitrus and the outsourced personnel for their commitment, zeal and efforts so that goals were met within the deadlines set and with maximum quality.

Lastly, we would like to express our appreciation to the Fundecitrus Management Board for its approval and trust, which were fundamental for us to be able to deliver the current portrait of our citriculture to all links of the productive chain at the same time, confirming our commitment to democratizing the information on this important sector.

--	----

1 – INTRODUCTION

This publication presents the results of the fifth survey on the tree inventory of São Paulo and West-Southwest Minas Gerais citrus belt carried out by Fundecitrus in cooperation with Markestrat, FEARP/USP and the department of math and science at FCAV/Unesp from January 2019 to May 2019.

Fundecitrus has carried out, starting from 2014 – year it took over the responsibility of performing a public and reliable forecast of the crop and the profile of groves – all activities involving field data collection, laboratory work and information processing. Since then, (Voluntary) Professor José Carlos Barbosa, from the department of math and science at FCAV/Unesp has been in charge of analyzing methodologies. Markestrat, represented by Vinícius Gustavo Trombin, is responsible for the survey governance, with professor Marcos Fava Neves of FEA-RP/USP and also linked to Markestrat serving as the institutional and methodological coordinator.

One of the governance measures adopted at the time of survey implementation that is still in force is the follow-up on activities being performed, which is done by a technical committee comprising citrus growers, representatives of orange juice companies, academics, as well as Fundecitrus researchers and supervisors. The committee aims at monitoring the performance of field activities and proposing solutions toward operational improvements.

Results from this study were obtained all along the survey, then compiled and restricted until the crop announcement date to the following professionals: Antonio Juliano Ayres (Fundecitrus general manager); Fernando Alvarinho Delgado and Roseli Reina (PES supervisors); Vinícius Gustavo Trombin (executive coordinator linked to Markestrat); Marcos Fava Neves (institutional and methodological coordinator linked to FEA-RP/USP and Markestrat); and José Carlos Barbosa (methodology analyst, working as a volunteer linked to the department of math and science of FCAV/Unesp). All of them were subject to confidentiality obligations regarding PES information before its announcement is made public, according to agreements signed between each of them and Fundecitrus.

As for antitrust practices, all of them are complied with through the adoption of measures necessary to prevent any communication or sharing of individual information with competitive content among the orange juice companies that collaborate with Fundecitrus in this project or between them and citrus growers.

1.1 – BUDGET

On April 26, 2018, the Fundecitrus Management Board formally approved this survey, with an allowed budget of R\$ 6.396 million, of which 56% refer to expenses with technical and administrative staff and labor-related charges; 30% to travel expenses, accommodations, meals and maintenance; and the remaining 14% refer to expenses with software licenses, IT equipment, supplies, indemnity for tree stripping and others. This budget provides financial support to activities performed until May 31, 2019. After that date the budget referring to the period from June 2019 to May 2020 will come into force.

1.2 – GENERAL FIGURES

- **More than 120 professionals directly involved in the survey;**
Field personnel: 40 agents and 56 assistants.
Laboratory personnel: 23 assistants.
Office personnel: 1 coordinator and 2 supervisors.
- **More than 400,000 kilometers covered from January to April 2019;**
Accumulated distance in travelling to count 5% of orange plots: 180,498 km.
Accumulated distance in travelling to strip orange trees: 231,317 km.
- **248 cities visited.**

1.3 – DEFINITION OF TECHNICAL TERMS

Citrus belt: region in Brazil with the largest concentration of commercial orange producing farms, encompassing cities in the state of São Paulo as well as some located in the West-Southwest state of Minas Gerais.

Farm: rural estate with continuous area of land (physical interruptions may be present such as roads and water streams) under the control of one owner, with more than 200 citrus trees, with the possibility of there being areas in the same estate that are allocated for different purposes such as growing other crops or raising livestock.

Plot: farm fraction or portion separated by lanes, roads, tracks or any other passageway that is usually wider than the spacing between planting rows.

Non-bearing tree: tree planted in 2017 or 2018 that has not yet entered into production.

Bearing tree: tree planted in 2016 or in previous years.

Dead tree: defoliated tree where at least 75% of branches are dry, with no evidence of recovery.

Vacancy: empty space on the ground within the planting row that should be occupied by a citrus tree, according to the tree spacing defined when the plot was planted.

Planting hole: central spot in the space occupied by each tree (plant-area) where the earth is dug out and a nursery plant is set; spot in the planting row where there is a potential tree.

Young grove: plot planted in 2017 or 2018. Plots planted in 2019 were not accounted for in this inventory since the field data survey included only the first quarter of said year.

Mature grove: plot planted in 2016 or in previous years.

Eradicated grove: area where citrus trees were removed, which can refer to the whole plot or to part of it.

Box: one orange box is equivalent to 40.8 kg or 90 lb.

Hectare: one hectare is equivalent to 2.4710439 US acres.

Kilometer: one kilometer is equivalent to 0.621371192 miles.

2 – METHODOLOGICAL PROCEDURES

2.1 – OBJECTIVE METHOD FOR MAPPING CITRUS GROVES

The second mapping of groves performed by Fundecitrus used georeferenced and high definition orthorectified images that enable precise measurements to be made. Images were obtained by satellites SPOT 6&7 from the European operator Airbus Defence and Space from May to August 2017. The georeferenced mapping was performed by survey agents *in situ*, that is, in person, on each citrus farm located in the 347 cities included in the 151,000 km² of images, from September 08, 2017 to January 29, 2018.

Data for each plot included variety, planting year, area occupied exclusively by trees, spacing, visual aspect of plants and irrigation system, if any. Only for a fraction of 1% of the mapped area, data was estimated by remote sensing and statistical inference. The data volume was encrypted and saved to the Fundecitrus Geographic Information System to form a new primary database (2018), to be stored until next mapping, expected to be performed in the second half of 2020 for the 2021 inventory to be taken.

2.2 – OBJECTIVE METHOD FOR TAKING THE ORANGE TREE INVENTORY

For the tree inventory, 5% of plots in the primary base (2018) are drawn to be visited and to have their planting holes classified and quantified. Each tree present in a plot was classified into up to four age categories: zero (up to two years old), one (from three to five years old), two (from six to ten years old) and three (over 10 years old). Dead trees and vacancies were also accounted for.

For the categorized counting, survey agents are informed by the citrus grower whether a grove has been reset and when. Next, they visit the block and define the visual pattern of the tree for each age category present in the plot, by combining the information provided by the citrus grower with visual evidence such as trunk circumference, height and shape of canopy.

If eradicated plots are found among the drawn plots, their areas are used to calculate the eradication rate of the sample. This proportion, called eradication rate, is applied to the primary base. The same calculation is done in case abandoned plots are found. After those two rates are applied to the primary base, the estimated area occupied by groves in the current crop is determined. This new area multiplied by the tree density of the primary base results in its updated number of planting holes. That number in turn is corrected by the index generated from the comparison between the number of planting holes found in the sample and its respective number in the primary base. Indexes resulting from counts are applied to that number of planting holes, i.e., percentages of trees in each age category, as well as percentages of dead trees and vacancies, aiming at the determination of the new tree inventory.

In years when farm mapping is not performed, as it is the case in this 2019 inventory, an estimate is made of plantings that occurred in the years following the most recent mapping. Hence, all farms in the sample are checked for the presence of groves planted after the survey agent's visit at the time the previous mapping was performed to form the primary base. An index for new plantings is generated from the rate between the additional area and the respective total area for each variety on the farm. Indexes per variety are extrapolated to the whole region to estimate plantings in the year.

Data used to estimate the number of trees planted is supplied by the São Paulo State animal and plant health protection agency (CDA-SP), of the São Paulo State department of agriculture and supply, on the number of citrus nursery plants marketed under the permit to transit plants (PTV) in the state of São Paulo.

In strata where stratified plantings per region and variety in the field survey show a higher number of trees than that supplied by the CDA-SP, the field survey data prevails. This difference results from the production of nursery plants by growers in nurseries within their farms and allocated to their own use, without the need of a permit to transit plants. Therefore, the final number of nursery plants planted in a given year includes nursery plants produced with and without permits to transit plants. To estimate the area of newly planted groves, their stratified average density per variety and region is used. From the sum of the number of trees supplied by the CDA-SP and that found in the survey with growers, nursery plants used for resetting are subtracted so that the number of trees planted in groves is estimated for that year.

Plots are randomly drawn for counting through the proportional stratified sampling technique. Stratification variables are: 12 regions, five orange variety groups and four age groups, totaling 240 strata. Counting of groves was concentrated between January 07 and March 08, 2019. Each survey agent counted an average of 15,500 planting holes per day.

2.3 – CITRUS BELT STRATIFICATION

Sectors and regions

The citrus belt is divided into five sectors that in turn are subdivided into 12 regions. Each region comprises several cities and has been named after one of them for reference. The division considered the soil and climate characteristics and historical aspects related to citriculture development that, in general, resulted in a technological pattern for similar farms in the region. Figure 1 presents sectors and regions of the citrus belt and following that, Chart 1 details the cities and abbreviations used to designate regions.

Figure 1 – Division of the citrus belt into 12 regions and respective sectors

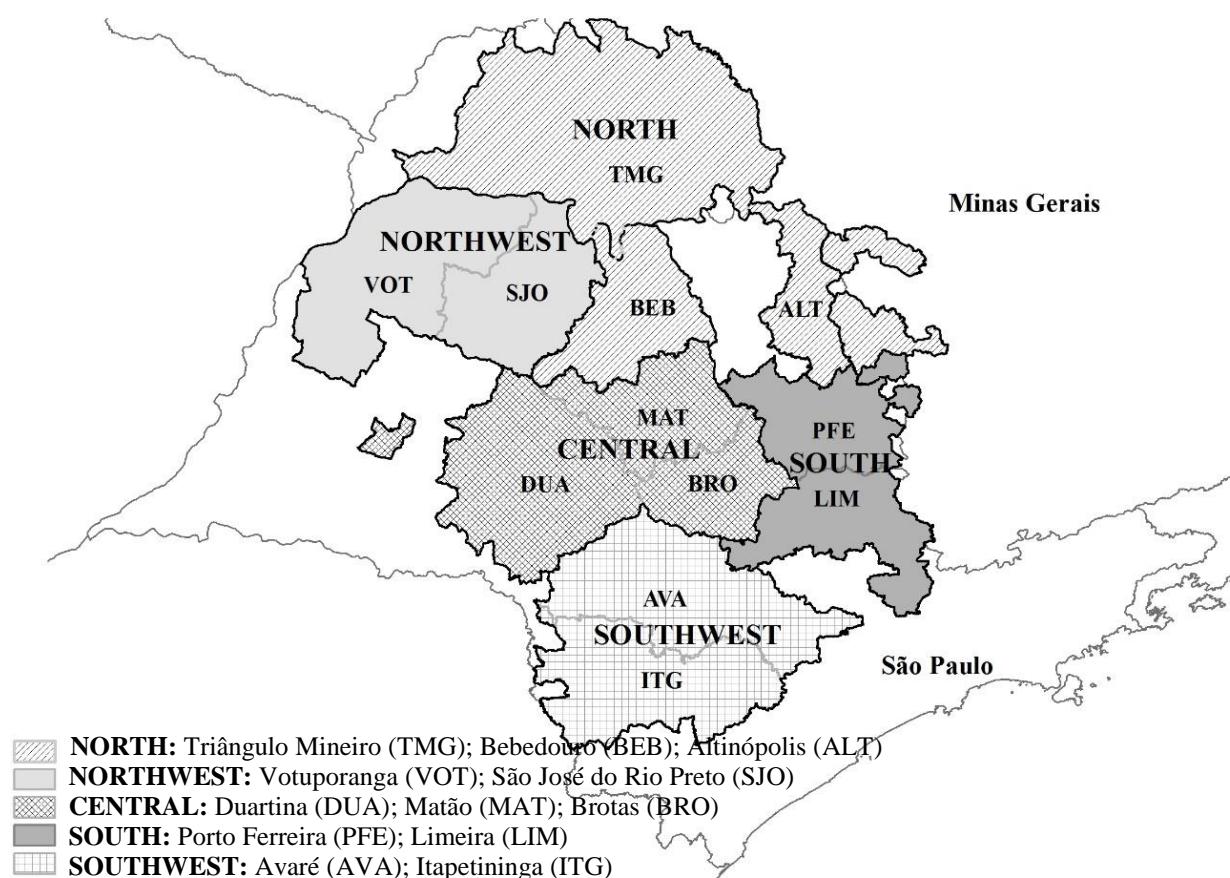

Chart 1 – Division of cities with citrus farms in sectors and regions

Sector	Region	Cities
North 72 cities	Triângulo Mineiro (TMG) 16 cities	Campina Verde, Campo Florido, Canápolis, Comendador Gomes, Conceição das Alagoas, Frutal, Gurinhatã, Itapagipe, Ituiutaba, Iturama, Monte Alegre de Minas, Planura, Prata, São Francisco de Sales, Uberaba, Uberlândia.
	Bebedouro (BEB) 35 cities	Ariranha, Barretos, Bebedouro, Cajobi, Catanduva, Catiguá, Colina, Colômbia, Elisiário, Embaúba, Guaraci, Ibirá, Irapuã, Itajobi, Marapoama, Monte Azul Paulista, Novais, Olímpia, Palmares Paulista, Paraíso, Pindorama, Pirangi, Pitangueiras, Sales, Santa Adélia, Severínia, Tabapuã, Taiaçu, Taiúva, Taquaral, Terra Roxa, Uchoa, Urupês, Viradouro, Vista Alegre do Alto.
	Altinópolis (ALT) 21 cities	Altinópolis, Batatais, Brodowski, Cajuru, Cássia dos Coqueiros, Cristais Paulista, Fortaleza de Minas, Franca, Ibiraci, Igarapava, Itamogi, Jacuí, Jeriquara, Monte Santo de Minas, Nova Resende, Patrocínio Paulista, Pedregulho, Santo Antônio da Alegria, São Pedro da União, São Sebastião do Paraíso, São Tomás de Aquino.
Northwest 91 cities	Votuporanga (VOT) 54 cities	Álvares Florence, Américo de Campos, Andradina, Aparecida d'Oeste, Aspásia, Auriflama, Cardoso, Dirce Reis, Dolcinópolis, Estrela d'Oeste, Fernandópolis, General Salgado, Guaraçá, Guarani d'Oeste, Guzolândia, Indiaporã, Jales, Macedônia, Marinópolis, Meridiano, Mesópolis, Mira Estrela, Mirandópolis, Murutinga do South, Nova Canaã Paulista, Ouroeste, Palmeira d'Oeste, Paranapuã, Parisi, Pedranópolis, Pereira Barreto, Pontalinda, Pontes Gestal, Populina, Riolândia, Rubinéia, Santa Albertina, Santa Clara d'Oeste, Santa Fé do South, Santa Rita d'Oeste, Santa Salete, Santana da Ponte Pensa, Santo Antônio do Aracanguá, São Francisco, São João das Duas Pontes, São João de Iracema, Sud Mennucci, Suzanápolis, Três Fronteiras, Turmalina, Urânia, Valentim Gentil, Votorantim Cachoeira, Votuporanga.
	São José do Rio Preto (SJO) 37 cities	Adolfo, Altair, Bady Bassitt, Bálzano, Cedral, Cosmorama, Floreal, Guapiaçu, Icém, Ipiguá, Jaci, José Bonifácio, Macaúbal, Magda, Mendonça, Mirassol, Mirassolândia, Monções, Monte Aprazível, Neves Paulista, Nhandeara, Nipoã, Nova Aliança, Nova Granada, Ónda Verde, Orindiúva, Palestina, Paulo de Faria, Planalto, Poloni, Potirendaba, São José do Rio Preto, Sebastianópolis do South, Tanabi, Ubarana, União Paulista, Zacarias.
Central 79 cities	Matão (MAT) 21 cities	Américo Brasiliense, Araraquara, Bariri, Boa Esperança do South, Borborema, Cândido Rodrigues, Fernando Prestes, Gavião Peixoto, Ibitinga, Itaju, Itápolis, Jaboticabal, Matão, Monte Alto, Motuca, Nova Europa, Novo Horizonte, Rincão, Santa Lúcia, Tabatinga, Taquaritinga.
	Duartina (DUA) 43 cities	Agudos, Álvaro de Carvalho, Alvinlândia, Arealva, Avaí, Balbinos, Bastos, Bauru, Boracéia, Cabrália Paulista, Cafelândia, Campos Novos Paulista, Duartina, Echaporã, Espírito Santo do Turvo, Fernão, Gália, Garça, Getulina, Guaiçara, Guaimbê, Guarantã, Iacanga, Júlio Mesquita, Lins, Lucianópolis, Lupércio, Marília, Ocauçu, Parapuã, Paulistânia, Pederneiras, Pirajuí, Piratinha, Pongá, Presidente Alves, Promissão, Reginópolis, Sabino, Santa Cruz do Rio Pardo, São Pedro do Turvo, Ubirajara, Uru.
	Brotas (BRO) 15 cities	Analândia, Bocaina, Brotas, Corumbataí, Dois Córregos, Dourado, Ibaté, Itirapina, Mineiros do Tietê, Ribeirão Bonito, Santa Maria da Serra, São Carlos, São Pedro, Torrinha, Trabiju.
South 54 cities	Porto Ferreira (PFE) 20 cities	Aguaiá, Caconde, Casa Branca, Descalvado, Guaranésia, Guaxupé, Itobi, Luís Antônio, Mococa, Pirassununga, Porto Ferreira, Santa Cruz da Conceição, Santa Cruz das Palmeiras, Santa Rita do Passa Quatro, Santa Rosa de Viterbo, São João da Boa Vista, São José do Rio Pardo, São Simão, Tambaú, Vargem Grande do Sul.
	Limeira (LIM) 34 cities	Águas de Lindóia, Americana, Amparo, Araras, Artur Nogueira, Atibaia, Bragança Paulista, Charqueada, Conchal, Cordeirópolis, Cosmópolis, Engenheiro Coelho, Espírito Santo do Pinhal, Estiva Gerbi, Holambra, Ipeúna, Iracemápolis, Itapira, Itatiba, Jaguariúna, Jarinu, Leme, Limeira, Lindóia, Mogi Guaçu, Mogi Mirim, Monte Alegre do South, Paulínia, Pinhalzinho, Piracicaba, Rio Claro, Santo Antônio de Posse, Serra Negra, Socorro.
Southwest 51 cities	Avaré (AVA) 31 cities	Águas de Santa Bárbara, Angatuba, Anhembi, Araçoiaba da Serra, Arandu, Avaré, Bofete, Borebi, Botucatu, Cabreúva, Capela do Alto, Cerqueira César, Cesário Lange, Conchas, Guareí, Iaras, Iperó, Itatinga, Lençóis Paulista, Manduri, Óleo, Pardinho, Porangaba, Porto Feliz, Pratânia, Quadra, Salto de Pirapora, São Manuel, Sorocaba, Tatuí, Tietê.
	Itapetininga (ITG) 20 cities	Alambari, Buri, Campina do Monte Alegre, Capão Bonito, Coronel Mamede, Itaberá, Itaí, Itapetininga, Itapeva, Itaporanga, Itararé, Nova Campina, Paranapanema, Pilar do South, São Miguel Arcanjo, Sarapuí, Sarutaiá, Taquarituba, Taquarivaí, Tejupá.
5 sectors	12 regions	347 cities with citrus farms

Variety groups

Chart 2 – Division of citrus species per variety group

Group of citrus species	Varieties
Oranges.....	Early: Hamlin, Westin and Rubi Other early: Valencia Americana ¹ , Seleta and Pineapple Mid-season: Pera Rio Late: Valencia and Valencia Folha Murcha Late: Natal
Other oranges.....	Washington Navel and Baianinha Charmute de Brotas Acidless sweet oranges and sweet lime: Lima Verde, Lima Late, Piralima, Lima Sorocaba, Lima Roque, João Nunes and Palestine sweet lime Other varieties
Acid limes and lemons.....	Tahiti acid lime (Persian lime) and Galego acid lime (Mexican lime) Sicilian lemon Other varieties including non-identified ones
Tangerines.....	Ponkan Murgott Other tangerines

¹ Plots registered as Valencia Argentina in the 2015 mapping were updated to Valencia Americana in this mapping

Age groups

Chart 3 – Classification by tree planting years and grove age groups

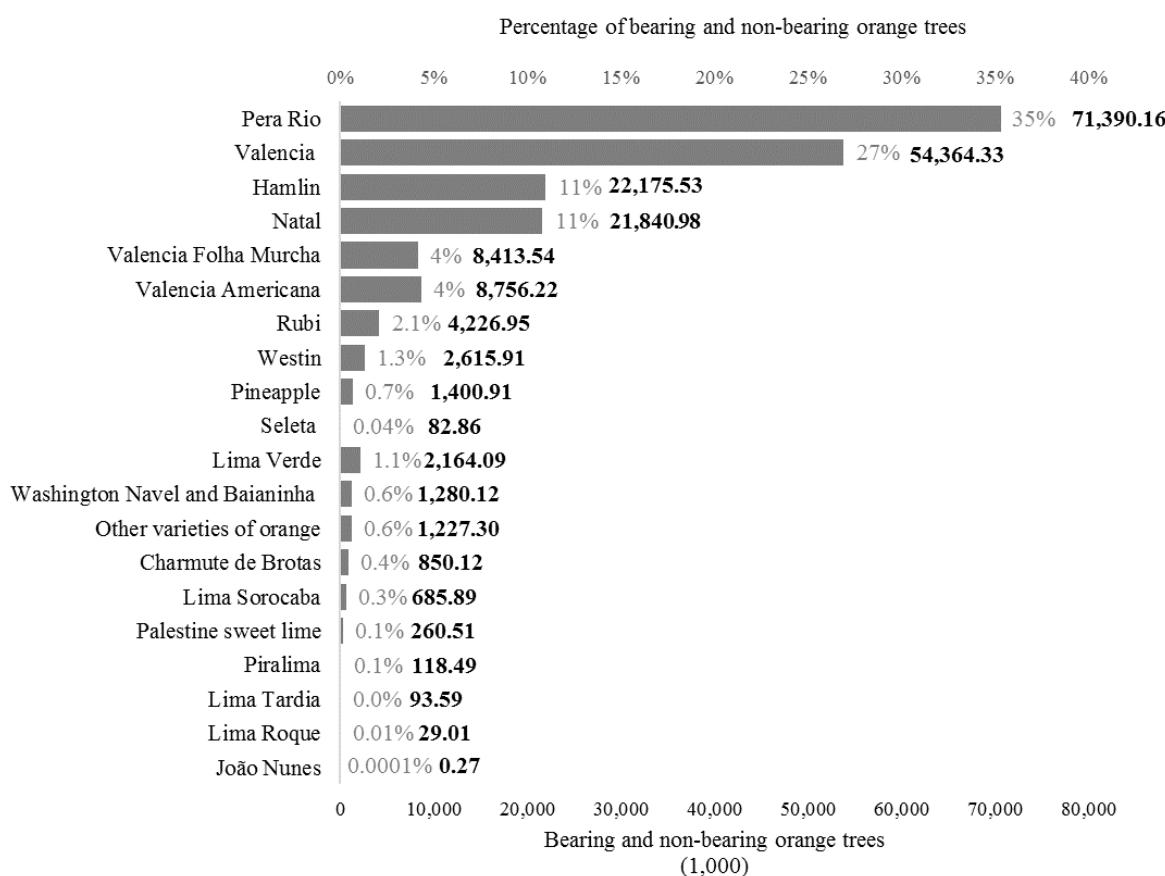

Age group	Planting years
1 to 2 years.....	2018, 2017
3 to 5 years.....	2016, 2015, 2014
6 to 10 years.....	2013, 2012, 2011, 2010, 2009
Over 10 years.....	2008 and previous years

3 – RESULTS

3.1 – MAIN CONCLUSIONS ON THE TREE INVENTORY

This publication presents the fifth tree inventory taken by Fundecitrus and portrays the estimated status of citrus groves in the São Paulo and West-Southwest Minas Gerais citrus belt, updated in March 2019. Data on groves of acid limes, lemons and tangerines, as well the number of farms and the percentage of irrigated area are the same presented in the 2018 inventory because their updating depends on a scan of the whole citrus planted area, scheduled to start in the second half of 2020, for the 2021 inventory to be taken. The number of 5,882 orange growing farms also remains unchanged until a new mapping is performed, but the data on their orange groves has been updated in this 2019 inventory, by means of a survey sampling 5% of the plots in the area, which enables a reassessment of the area and the percentage of trees in each age category, dead trees and vacancies in groves.

The 2019 sample survey showed that the area planted with orange groves, including all varieties, totals 408,825 hectares, which is 1.33% smaller as compared to the figure in the 2018 inventory. Of this total, 395,764 hectares, that is, 97% of that area, are planted with the varieties Hamlin, Westin, Rubi, Valencia Americana, Seleta, Pineapple, Pera Rio, Valencia, Valencia Folha Murcha and Natal. These varieties comprise the group called “oranges” in the tables in this report. The remaining 3%, that is, 13,061 hectares, comprise the group called “other oranges” with the varieties Bahia, Baianinha, Charmute de Brotas, acidless sweet oranges, sweet lime and others. Graph 1 shows the complete distribution of the volume of trees per variety and their share in relation to the total orange trees.

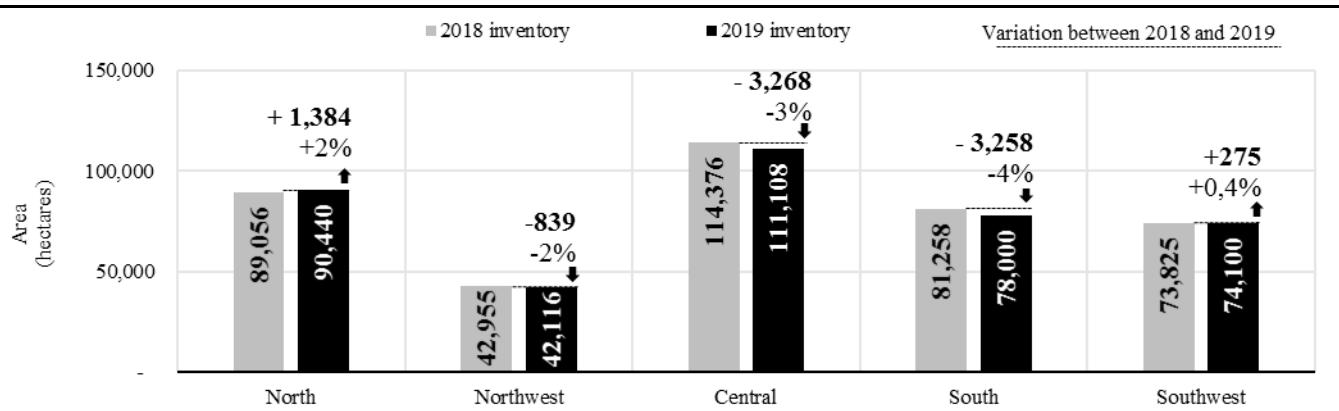

Graph 1 – Oranges and other oranges: Distribution of bearing and non-bearing orange trees per variety

From this point on in the text, just like in previous inventories, statements are specific to the group called oranges, which is more representative of the citrus belt.

The area with groves of the main varieties of oranges (395,764 hectares) presented in this inventory is 5,706 hectares smaller than that in 2018. This decrease corresponds to a net variation of -1.42%. This figure is determined from the area of groves in the 2018 inventory (401,470 hectares) to which the expansion area (8,474 hectares) relative to plantings in new areas in 2018 was added, as well as the area of currently recovered groves, accounted for as abandoned in 2018 (468 hectares). From this total, the area accounted for as having bearing trees in the previous inventory but that is now abandoned (1,521 hectares) is deducted. Eradicated areas that were not replanted with orange (13,127 hectares) in 2018 are also deducted.

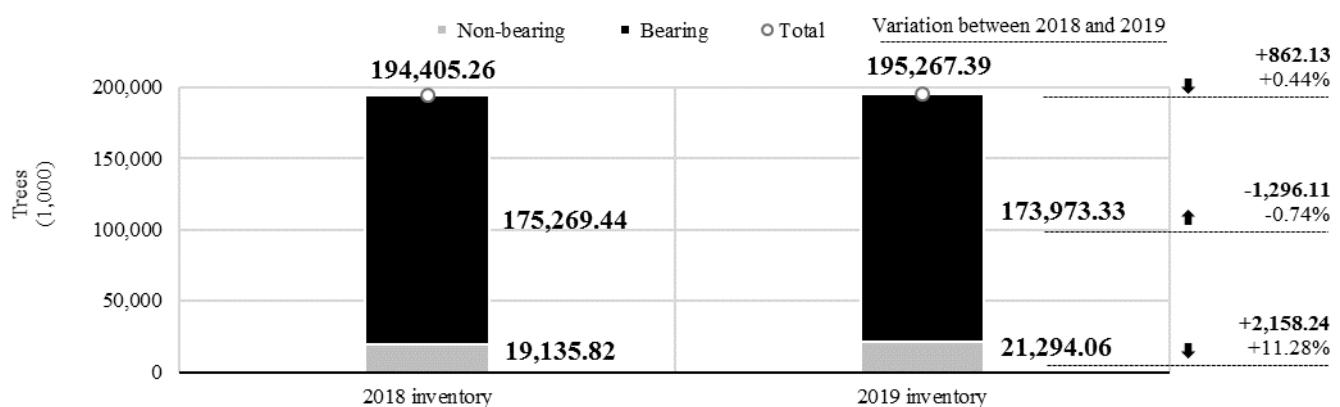

The area of groves planted in 2018 totals 13,532 hectares. Of this total, 63% are plantings that occurred in expansion areas and 37% in renovation areas. In the varietal distribution, the Pera Rio variety accounts for 38% of these plantings; Valencia for 23%; Natal for 11%; Hamlin for 8%; Valencia Americana for 8%; Rubi for 4%; Valencia Folha Murcha for 4%; and Westin, Pineapple and Seleta altogether for approximately 4%. The probable explanation for a greater interest in Pera Rio is the quality of its fruit for fresh consumption and juice processing. New groves are well distributed in all sectors of the citrus belt, in that 23% of them are in the North sector; 17% in the Northwest sector; 24% in the Central sector; 19% in the South sector and 17% in the Southwest sector. This data is estimated, actual figures will be disclosed after the next scan of the citrus belt. Once data is confirmed, the trend of increased planting will be proven true, with a rise of approximately 10% as compared to the area planted in 2017, or approximately 3.5% in relation to the total area, which is still slight.

Among the five sectors of the citrus belt only the North and Southwest sectors present a positive variation of the area planted with orange as compared to the previous inventory, as shown in Graph 2. This balance indicates that the loss of groves was less significant in those sectors, which should be related to lower greening incidence rates. According to the survey carried out by Fundecitrus in 2018, symptomatic trees are present in 5.21% of groves in the North sector, 8.20% of groves in the Southwest sector, and more than 30% of groves in the Central and South sectors. The negative balance in the Northwest sector, in addition to being affected by the water deficit and higher temperatures resulting in lower yield, was probably more influenced by citrus canker, since according to the same survey, the disease is present in approximately half of the plots and 40% of the trees, in addition to the water deficit and higher temperatures resulting in lower yield.

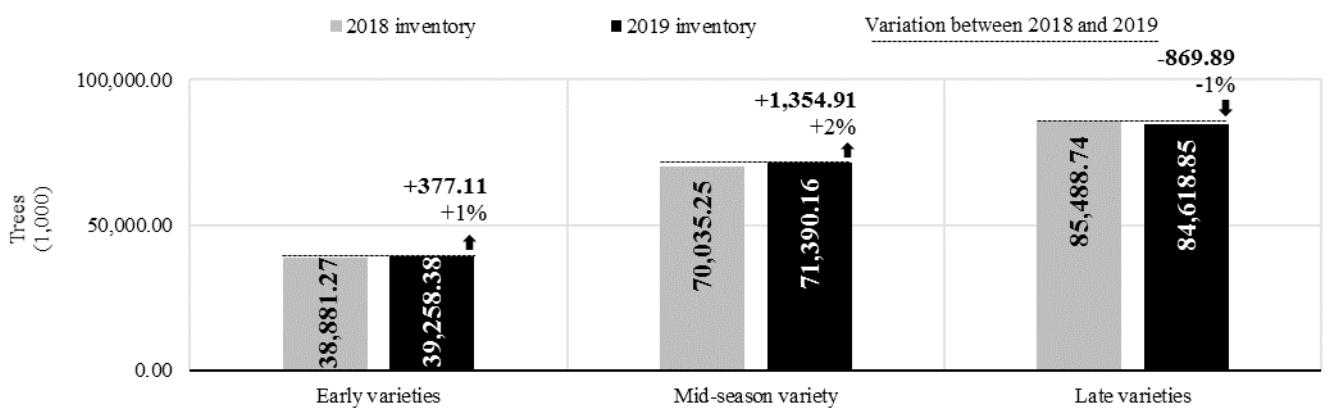

Graph 2 – Oranges: Area of groves per sector [2018 and 2019 inventories]

Bearing orange trees add up to 173.97 million and non-bearing orange trees to 21.29 million, totaling 195.27 million trees. In comparison to the 2018 inventory, the total increase in trees was of approximately 862 thousand, which is equivalent to 0.44%, as shown in Graph 3. This data points to the continuity of the scenario of previous years of a reduction that is sharper in area than in number of trees, which results from the eradication of low-density groves and planting of denser groves.

Graph 3 – Oranges: total trees, bearing and non-bearing trees [2018 and 2019 inventories]

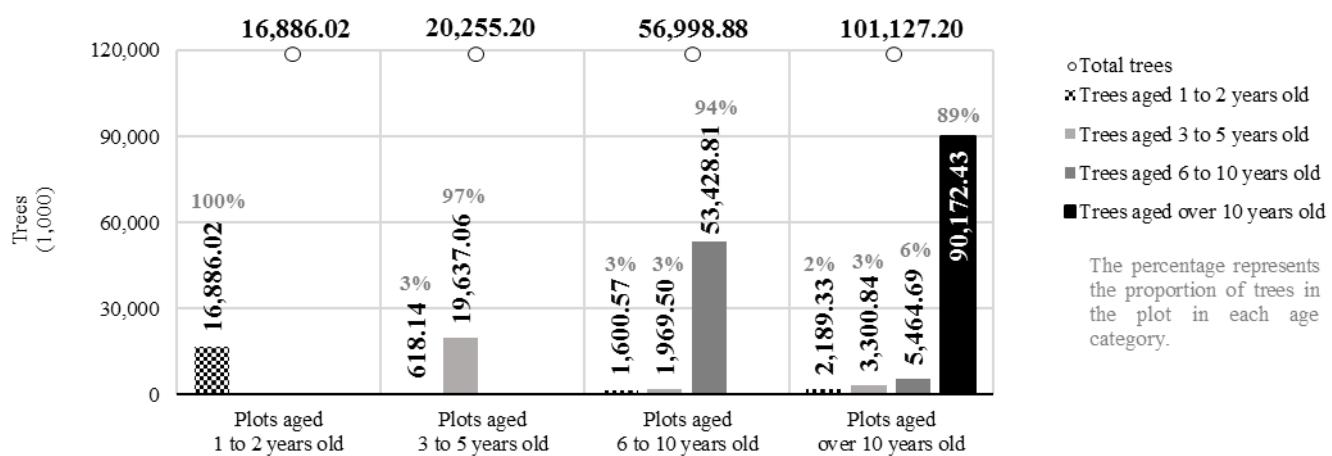

The distribution of citrus varieties by fruit harvesting time shows that the share of trees of early varieties in relation to the total 195.27 million trees increased approximately 1%, whereas the share of mid-season varieties increased 2% and that of late varieties decreased 1%, in comparison to the previous inventory. Currently, 39.6 million trees are of early varieties, usually harvested between May and August; 71.39 million are of mid-season varieties, usually harvested between July and October; and 84.62 million are of late varieties, usually harvested between October and January, as shown in Graph 4. Climatic variations and other factors such as crop size and fruit maturity stage may advance or extend the harvesting time from one year to the next.

Graph 4 – Oranges: Trees grouped by maturity time of varieties [2018 and 2019 inventories]

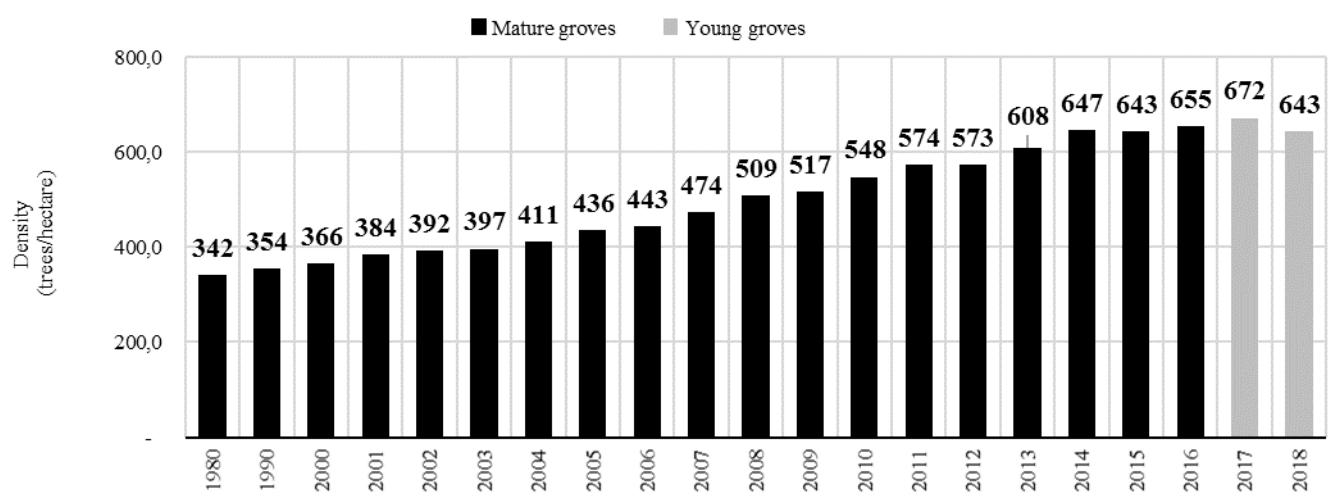

The average age of mature groves rose to 10.9 years. This systematic aging since the 2015 inventory results from more modest plantings observed in the last five years. The share of groves of up to ten years old in the total area equaled 46% in the previous inventory and decreased to 40% in this one; groves from 11 to 15 years old increased their share from 34% to 36%; those from 16 to 20 years old increased their share from 12% to 15%; and those over 20 years old remained with their share of 9%.

Groves of up to two years old, that is, planted in 2017 and 2018, comprise 16.89 million non-bearing trees. Groves from three to five years old, planted from 2014 to 2016, comprise 20.26 million trees – approximately 97% of those trees are in the same age group of plots and 3% are resets of the age group of one to two years old. Groves from six to ten years old were planted from 2009 to 2013 and comprise approximately 56.99 million trees; 94% of trees remain in the category of six to ten years old (same age group of plots); 3% are in the age group of three to five years old; and 3% are in the age group from one to two years old. In the group of groves over ten years old, that is, planted until 2008 and totaling 101.13 million trees, 89% of trees are over ten years old; 6% are between six and ten years old; 3% are between three and five years old; and 2% are between one and two years old. Graph 5 shows the distribution of trees per age category in all age groups of groves.

Graph 5 – Oranges: Trees per age groups and age groups of plots

The average density of groves planted in 2018, as estimated by the sample survey, is 643 trees per hectare, as compared to 672 trees in groves planted in 2017, and 655 trees in groves planted in 2016. This data indicates a stabilization in the increased planting density trend, as highlighted in Graph 6. The average density of young groves in this inventory is 657 trees per hectare whereas for mature groves that density is 482 trees per hectare.

Graph 6 – Oranges: Average density of groves per planting year

The average eradication rate in the citrus belt is 4.53%, as estimated for the period from April 2018 to March 2019, which is slightly higher than the rate for the same period in the previous year (3.84%). The eradicated area is estimated to be 18,185 hectares. Of this total, 5,058 hectares have been renovated. Therefore, the net loss due to eradication is 13,127 hectares, in that 83% of this area is in the regions of Matão (24%), Limeira (20%), Porto Ferreira (16%), Duartina (12%) and Votuporanga (11%). Abandoned groves including all orange varieties totaled 5,115 hectares in the 2018 inventory, whereas in this inventory it was reduced to 3,148 hectares. Regions that concentrate approximately 80% of abandoned groves are: Limeira (28%), Brotas (18%), Votuporanga (15%), Matão (11%) and Bebedouro (7%). The percentage of dead trees in the citrus belt remained stable at 1.28% and vacancies correspond to 4.61% of existing planting holes.

3.2 – TABLES OF DATA

Calculations used whole numbers and all decimal points, the same way they are stored in the data bank. Occasional divergences between figures on tables result from rounding numbers. The word “oranges” in the title of tables indicates that their figures comprise the Hamlin, Westin, Rubi, Valencia Americana, Seleta, Pineapple, Pera Rio, Valencia, Natal and Valencia Folha Murcha varieties.

NA – Non-available data, as 2018 plantings took place after the mapping for the 2018 inventory.

(X) Not applicable.

¹ Information per planting year considers the year the original plot was planted and refers to remaining groves at the time data were collected to take inventory. Therefore, information does not depict the totality of groves established in such years, since eradication and renovation occurred along time.² Snapshot of groves in March of the year the inventory is published.³ Estimate of eradicated and abandoned groves from September 2017 to March 2019.⁴ Groves planted in 2016 belonged to the group of young groves in the 2018 inventory and moved to the group of mature groves in this 2019 inventory.

NA – Non-available data, as 2018 plantings took place after the mapping for the 2018 inventory.

(X) Not applicable.

¹ Information per planting year considers the year the original plot was planted and refers to remaining groves at the time data were collected to take inventory. Therefore, information does not depict the totality of groves established in such years, since eradication and renovation occurred along time.² Snapshot of groves in March of the year the inventory is published.³ Estimate of eradicated and abandoned groves from September 2017 to March 2019.⁴ Groves planted in 2016 belonged to the group of young groves in the 2018 inventory and moved to the group of mature groves in this 2019 inventory.⁵ Trees from resetting after the original plot was planted were estimated at their respective ages.

¹ Information per planting year considers the year the original plot was planted and refers to remaining groves at the time data were collected to take inventory. Therefore, information does not depict the totality of groves established in such years, since eradication and renovation occurred along time.

² Trees from resettings after the original plot was planted were estimated at their respective ages.

¹ Weighted average density per stratum area. Calculation for groves over 2 years of age considers the total trees of the plot, that is, bearing and non-bearing trees (resets of 2017 and 2018).

² Information per planting year considers the year the original plot was planted and refers to remaining groves at the time data were collected to take inventory. Therefore, information does not depict the totality of groves established in such years, since eradication and renovation occurred along time.

¹ The method employed for mapping groves of acid limes and lemons was reduced to the outline of the plots, and data about variety and number of trees were supplied by the farmer or person in charge. Whenever such information was not provided, the number of holes was calculated by the area of the plot divided by the spacing, which was identified by visual evaluation. The counting of 5% of the plots was not performed for this group of citrus species.

Table 96 – Tangerines: Area and planting holes¹ estimated by region, variety and age of plot [2018 inventory]

¹ The method employed for mapping tangerines groves was reduced to the outline of the plots, and data about variety and number of trees were supplied by the farmer or person in charge. Whenever such information was not provided, the number of holes was calculated by the area of the plot divided by the spacing, which was identified by visual evaluation. The counting of 5% of the plots was not performed for this group of citrus species.

3.3 – ABANDONED ORANGE GROVES

Abandoned groves are plots where no management signs are identified, therefore showing no pruning/mowing, insufficient plant health control, high infestation of pests and diseases, with frequent rotten fruit on the ground, and cattle present in the plot. In many cases, the grove degradation is so severe that it prevents agents entering to collect data such as tree spacing, planting year and variety.

Table 101 – Oranges: Area and percentage of abandoned groves in relation to the total area [2018 and 2019 inventories]

Sector and region	2018 inventory			2019 inventory			Percentage of abandoned area in relation to total
	Abandoned area found in the mapping (scan)	Abandoned area found in the 2018 sample survey	Total	Updated abandoned area found in the mapping (scan)	Abandoned area found in the 2019 sample survey (previously bearing groves, abandoned in 2018)	Total

2019-2020 ORANGE CROP FORECAST FOR SÃO PAULO AND WEST-SOUTHWEST MINAS GERAIS CITRUS BELT – MAY FORECAST

Published on May 24, 2019¹

Publication Schedule

2019-2020 Crop Year

2019-2020 Crop executive summary: May 10, 2019

March 2019 Tree inventory: May 24, 2019

Crop forecast: May 24, 2019

1st Crop forecast update: September 10, 2019

2nd Crop forecast update: December 10, 2019

3rd Crop forecast update: February 11, 2020

Final crop forecast: April 10, 2020

Throughout the crop year, the crop forecast will be updated in the months mentioned in the schedule above with data on fruit drop and fruit size (fruit per box) collected in the months previous to the forecast updates. With the aim of meeting the demands both from the citrus sector and the press, we reserve the right to enlarge, review and deepen the information already published. It is therefore recommended that the most recent publication available at www.fundecitrus.com.br be used.

¹ Year 5 – Nº 1 – May 24, 2019 (Portuguese version only)

Year 5 – Nº 2 – May 27, 2019 (Portuguese version only)

Year 5 – Nº 3 – May 29, 2019 (Portuguese and English versions)

Improvements resulting from text review and from information included are presented in a consolidated form on the last page of this report.

1 – 2019-2020 ORANGE CROP FORECAST

The 2019-2020 orange crop forecast for São Paulo and West-Southwest Minas Gerais citrus belt, published on May 10, 2019 by Fundecitrus in cooperation with Markestrat, FEA-RP/USP and FCAV/Unesp, is 388.89 million boxes (40.8 kg or 90 lb). The total orange production includes:

- 76.97 million boxes of the Hamlin, Westin and Rubi varieties;
- 19.75 million boxes of the Valencia Americana, Seleta and Pineapple varieties;
- 116.20 million boxes of the Pera Rio variety;
- 128.30 million boxes of Valencia and Valencia Folha Murcha varieties;
- 47.67 million boxes of the Natal variety.

27.21 million boxes of the estimated crop are expected to be produced in the Triângulo Mineiro.

The projected figure is 36% above the previous one of 285.98 million boxes, and 21% larger than the average crop size for the last ten years. Succeeding irregular crops in alternate years show the biennial production cycle of orange trees, as presented in Graph 1.

Graph 1 – Orange production from 1988-1989 to 2018-2019 and 2019-2020 crop forecast

Source: CitrusBR (1988-1989 to 2014-2015) and Fundecitrus (2015-2016 to 2019-2020)

In addition to the alternance in production, the climate favored bloom and fruit set, contrarily to what was observed in the last crop season. Average yield per hectare in this crop season is estimated at 1,051 boxes per hectare and 2.24 boxes per tree, which represents an increase in comparison to the 756 boxes per hectare and 1.63 boxes per tree harvested in the 2018-2019 crop.

Among citrus belt sectors, the Southwest presents the largest yield, with 1,227 boxes per hectare and 2.42 boxes per tree, keeping its position with above average rates and smaller variation between crop seasons, of exact 2.7% as compared to the yield of the previous cycle. The largest yield increases are seen in the Northwest and North sectors, of 128% and 78% respectively. Yield grew 47% in the Central sector and 22% in the South sector.

The expected yield per hectare this season is a historical record. In addition to the climate, which is a conjunctural factor, structural factors also contributed to such performance: protected nurseries, cultural practices especially related to nutrition and irrigation, high density groves, increased plantings in regions of more favorable climate, proper combination of rootstock and scion; control of CVC (citrus variegated chlorosis) and greening.

2 – OBJECTIVE SURVEY METHOD FOR THE ORANGE CROP FORECAST

In order to perform this estimate, the objective method used in previous crop seasons was maintained, which is based on quantitative data – field measurements, counting and weighing of fruits – applied to the equation represented below.

$$\text{Forecasted production} = \frac{\text{Bearing trees} \times \text{Fruit per tree} \times (1 - \text{Drop rate \%}) \times (1 - \text{CF \%})}{\text{Fruit per box}}$$

where CF is the correction factor

For increased critical mass and transparency, this survey has since its implementation developed activities with the follow-up from a technical committee organized in the 2015-2016 crop year with the purpose of offering operational improvement. This committee is made up by citrus growers, representatives of orange juice companies, academics, as well as Fundecitrus researchers and supervisors.

Results from the inventory and tree stripping were obtained throughout the survey, then compiled and restricted until the date of this publication to the following professionals: Antonio Juliano Ayres (Fundecitrus general manager); Fernando Alvarinho Delgado and Roseli Reina (PES supervisors); Vinícius Gustavo Trombin (executive coordinator linked to Markestrat); Marcos Fava Neves (political-institutional and methodological coordinator linked to FEA-RP/USP and Markestrat); and José Carlos Barbosa (methodology analyst linked to the department of math and science of FCAV/Unesp). All of them were subject to confidentiality obligations with regard to PES information before its announcement was made public, according to agreements signed between each of them and Fundecitrus. As for antitrust practices, they were all complied with through the adoption of measures necessary to prevent any communication or sharing of individual information with competitive content among the orange juice companies that collaborate with Fundecitrus in this project or between them and citrus growers.

This team, together with Fundecitrus vice-president Roberto Hugo Jank Junior, representing president Lourival Carmo Monaco, who was absent due to commitments abroad, concluded the crop forecast on May 10, 2019, at 9:30 a.m., in a closed meeting with no external communication channel beyond participants. Following that, at 10 a.m., Fundecitrus vice-president began the public announcement of the crop forecast at the Fundecitrus auditorium in Araraquara-SP, which was broadcast live on the website (www.fundecitrus.com.br). Fundecitrus general manager Antonio Juliano Ayres presented the detailed data. After the crop forecast announcement, the 2019-2020 Crop Executive Summary was made available on the Fundecitrus website.

Details on the estimate for the four components of the equation follow.

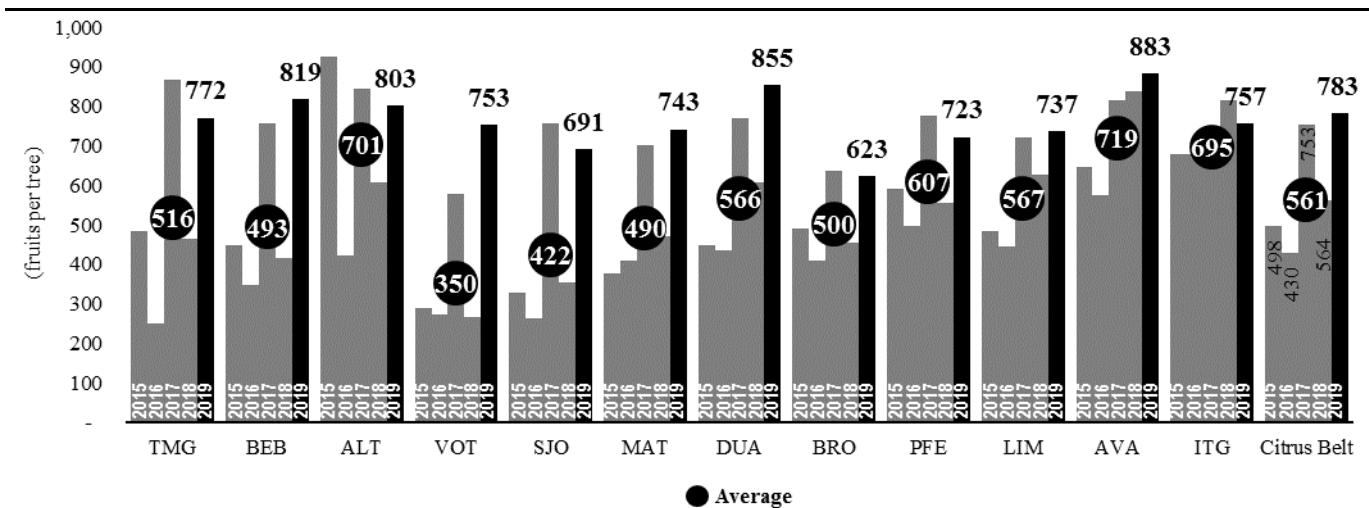

BEARING TREES

Bearing trees total 173.973 million, which is 0.74% below the previous inventory. Trees planted in 2016 and previous years are considered bearing trees in this crop. Varieties included in this estimate represent 97% of trees and also 97% of the area of orange groves comprising the inventory in the current crop year.

Information on bearing trees was obtained from the Tree Inventory of São Paulo and West-Southwest Minas Gerais Citrus Belt: Snapshot of Groves in March 2019, taken from the 2018 primary base – created by mapping groves from September 8, 2017 to January 29, 2018 – and from counting the trees present in 5% of orange plots, from January 7 to March 8, 2019.

FRUIT PER TREE

The average number of fruits per tree in April 2019, disregarding the fruit that will drop throughout the crop season, is 783. In this season, groves presented a more intense bloom determined both by the low production in the previous crop, with increased nutritional reserves in plants, and the long-term water stress trees were subject to during floral induction. Graph 2 shows the number of fruits per tree stripped in 2015 to 2019 in the citrus belt, and separately for each of the twelve regions.

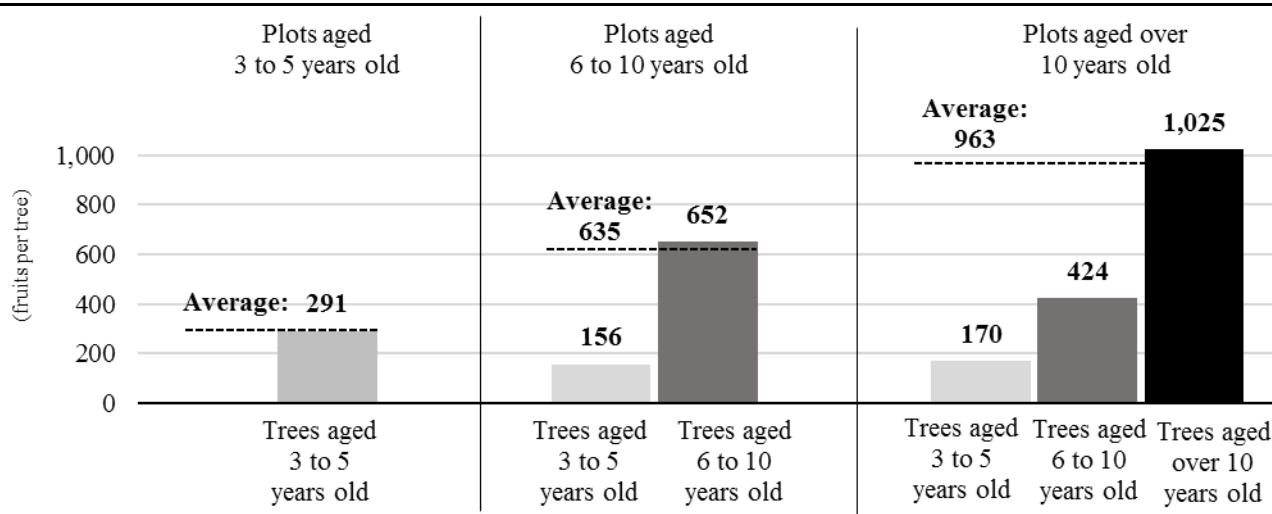

Graph 2 – Number of fruits per tree stripped in 2015 to 2019 per region

The average rainfall in the citrus belt from April to July 2018 totaled only 69 millimeters, which is nearly a third of the rain that usually falls in that time period (1981-2010). After the prolonged drought, non-irrigated groves bloomed following rains that fell in early August in the Central, South and Southwest sectors, and in mid-September, in the North and Northwest sectors. Regions where rains fell only in September have the largest concentration of irrigated areas in the citrus belt, except for Altinópolis, located in the North sector. In order to advance flowering, irrigation started in July 2018.

During post-bloom, temperatures remained mild. In some cities, maximum temperatures reached 35°C (95°F), although just for few consecutive days. In addition to mild temperatures, spring and summer rains kept the water available, favoring the setting of flowers and fruitlets, which resulted in a more homogeneous production.

The first bloom from July to September 2018, accounts for 84.1% of the total production. The second bloom, which started in October and November 2018, is estimated at 10.2%. Together, these blooms correspond to 94.3% of the production and should be harvested at the same time. The third bloom, in December 2018 and January 2019, corresponds to 3.2%. The fourth bloom, which started in February 2019, corresponds to 2.5%. For the forecast, all fruits from first, second and third blooms were fully considered. A fruit set rate of 33% was applied to fruits from the fourth bloom. In the separation of fruits per bloom, off-season fruits were also identified and resulted from late and sporadic flowers from the previous crop season, not accounted for in the current crop forecast.

The yield of three to five years old plots is 291 fruits per tree in this crop season. In six to ten years old plots an average of 635 fruits per tree is estimated, with 652 fruits per tree for original plantings and 156 fruits per tree for three to five years old resets. Plots over 10 years old have an expected average of 963 fruits per tree and a yield of 1,025 fruits per tree for the original plantings, 424 fruits per tree for six to ten years old resets and 170 fruits per tree for three to five years old resets. Yields are presented in Graph 3.

Ages and planting years: 1 to 2 years old (2017 and 2018), 3 to 5 years old (2014 to 2016), 6 to 10 years old (2009 to 2013) and over 10 years old (2008 and previous years).

Graph 3 – Age-stratified number of fruit per tree in the plot

The number of fruits per tree is closely related to the variety characteristics. When trees were stripped in April 2019, an average of 1,114 fruits per tree were counted for the group of early varieties Hamlin, Westin and Rubi. As already known, varieties of these groups are more productive than the others, therefore their production is estimated to be 42% above average in this crop season. Next in the sequence are the late variety Natal with 853 fruits per tree, the other early varieties with 834 fruits per tree, the late varieties Valencia and Valencia Folha Murcha with 735 fruits per tree, and last the Pera Rio variety with 665 fruits per tree.

The method used consists of tree stripping, that is, the advanced harvest of all fruits in the tree, regardless of the bloom they are from. Tree stripping in this crop season occurred in the period from March 14 to April 25, 2019. Fruit harvested was taken to a tree stripping laboratory in Araraquara, where each sample was separated into the different blooms they were from. Fruit was quantified by automatic counting equipment and then weighed.

A total of 2,560 trees were stripped. Trees were drawn for stripping in two phases. The first drawing, by the method of stratified random sampling, included 2,200 trees distributed proportionally to the total orange trees in the citrus belt and stratified according to their region, variety and age. The second drawing was aimed at increasing the estimate precision and included 360 resets of ages lower than those in the age groups of the groves they were part of. These resets correspond to replacements made mainly to offset tree losses caused by greening, citrus canker and other diseases. The tree population in this second drawing comprehends plots that were counted in full to update the inventory and that meet the stratification criteria.

The stratification factor “region” is comprised of 12 groups encompassing the 320 cities where there are farms with mature orange groves. In addition to the subdivision into the 12 regions, the following charts present the five subdivisions of the factor “variety” and the six subdivisions of the factor “age”. Combinations of these factors result in 360 strata.

Chart 1 – Make-up by sector of regions of the citrus belt included in the drawing

Chart 3 – Make-up of age groups from the combined age of plots and age of trees

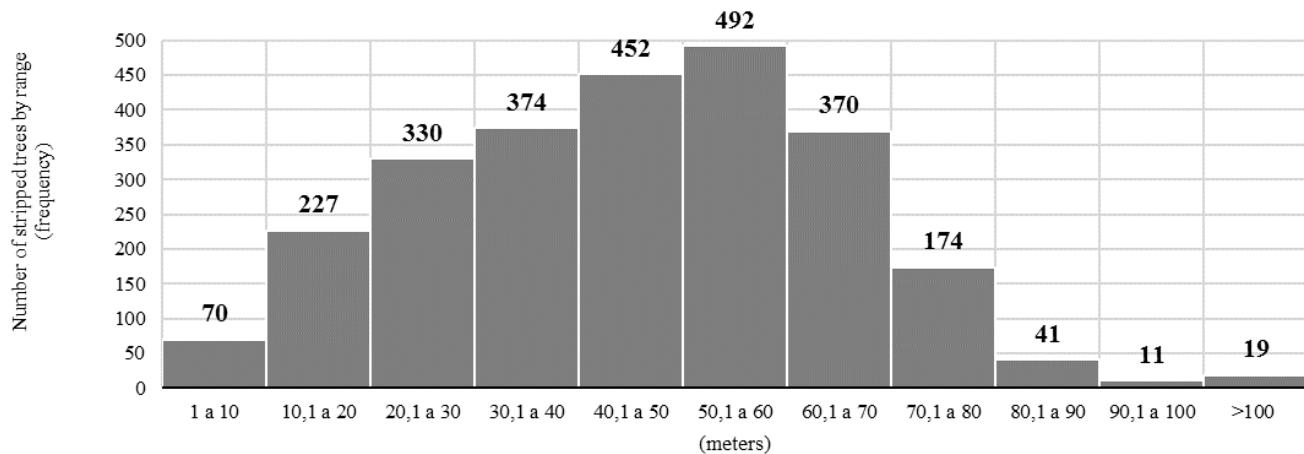

Age of plots ¹	Age of trees ²
3 to 5 years old.....	3 to 5 years old
6 to 10 years old.....	3 to 5 years old
6 to 10 years old.....	6 to 10 years old
Over 10 years old.....	3 to 5 years old
Over 10 years old.....	6 to 10 years old
Over 10 years old.....	Over 10 years old

¹ Ages and planting years: 1 to 2 years old (2017 and 2018), 3 to 5 years old (2014 to 2016), 6 to 10 years old (2009 to 2013) and over 10 years old (2008 and previous years).

² Estimated from information provided by growers on years resets were planted in the plot and from visual aspects of plants such as trunk circumference, height and shape of canopy, among other factors.

For the 2,200 trees in the first drawing, the location in the plot of the tree to be stripped is predetermined and varies every crop season. This makes the selection of the tree to be unbiased, that is, free from interference of the survey agent. Otherwise the choice could be skewed towards trees with more or less fruit. For the 2019-2020 crop, the tree in the drawn plot is the one located in the 22nd planting hole in the 11th row. In case there is a vacancy or dead tree in that position, or yet a tree of an age different from that of trees originally planted in the plot, the third plant down is selected. Should that situation repeat itself three more plants down are counted, until a tree of the drawn age is found. If the plot does not have 11 or more planting rows, the counting restarts in the existing rows until number 11 is reached. For the second drawing of 360 resets, the stripped tree is found in the plot after visual aspects are considered, such as trunk circumference and size of canopy.

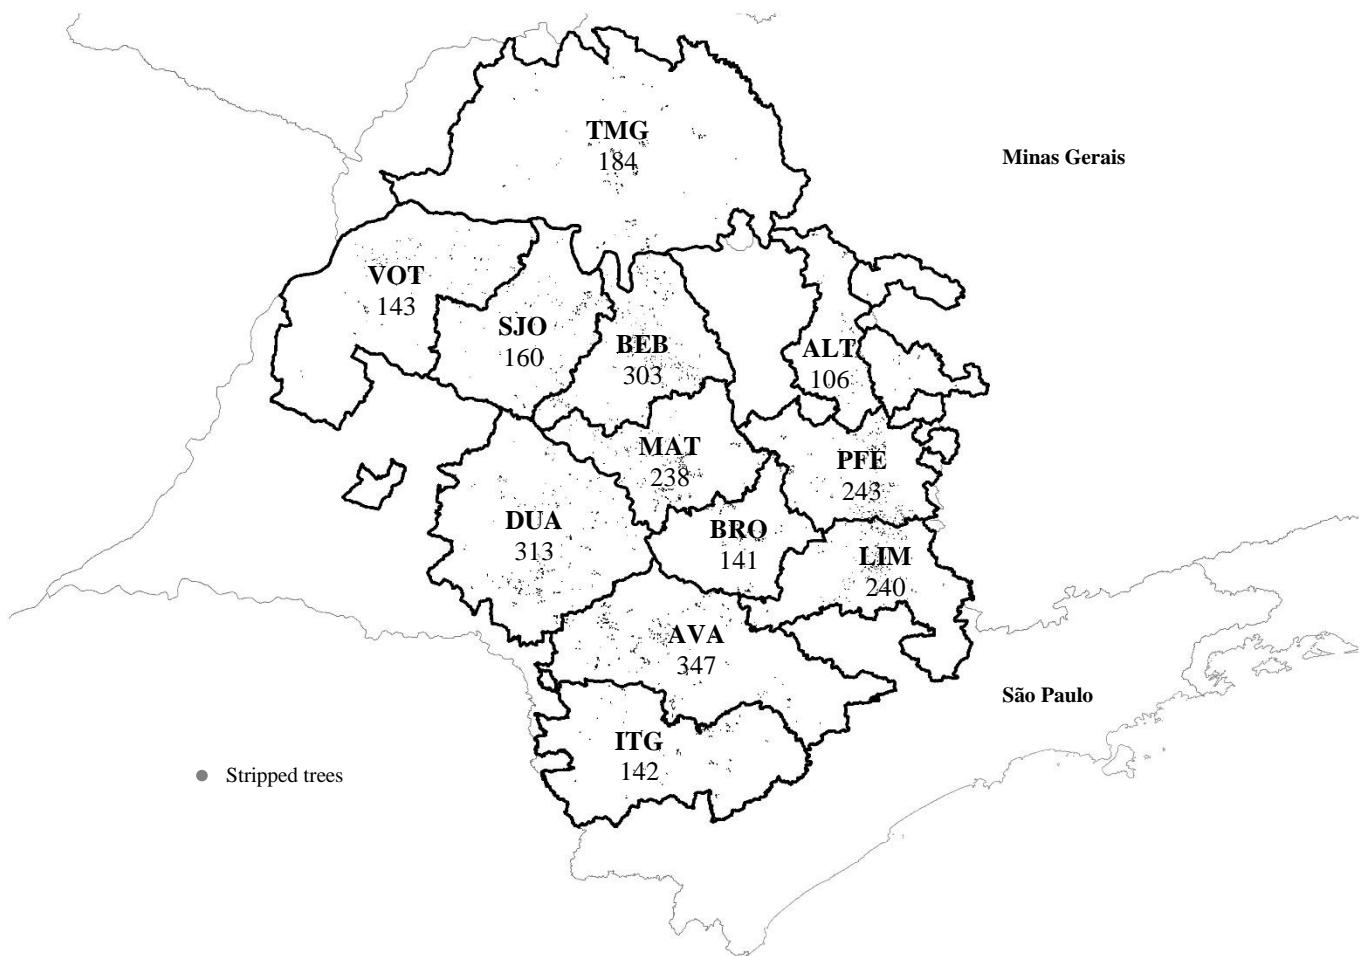

Graph 4 presents the distance (in meters) from the stripped tree to the nearest border of the plot, which shows the majority of ranges with similar frequencies, with a central figure between 50 and 60 meters of distance from the stripped tree to the nearest border. Most of the 70 plots with the shortest distances, from one to ten meters, are small – approximately 80% of them have up to four hectares.

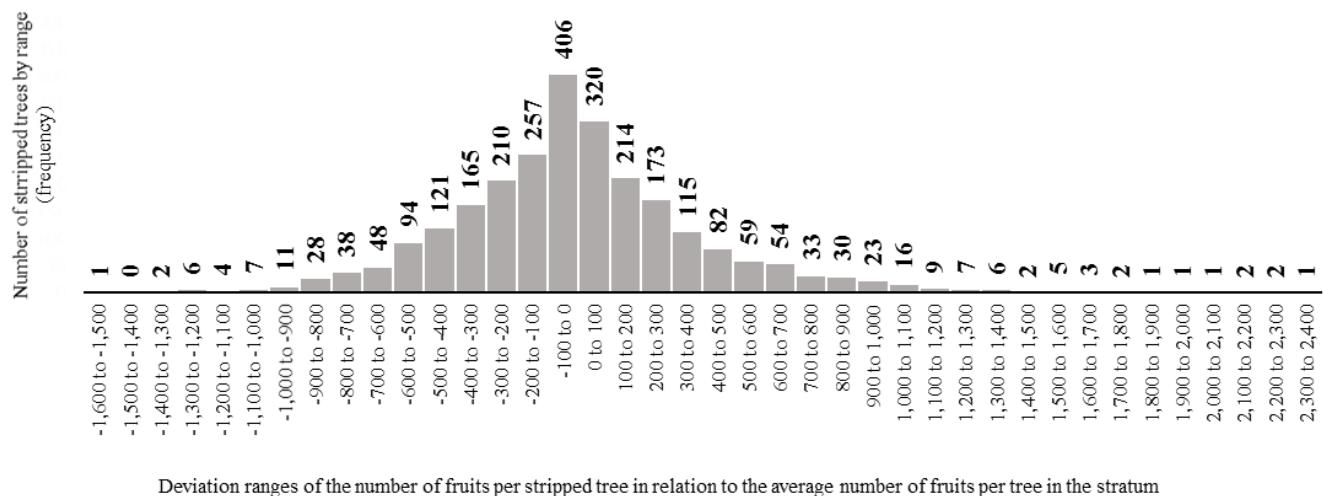

Graph 4 – Histogram of the distance from the stripped tree to the nearest border of the plot

Figure 1 shows the location and number of stripped trees in each sector of the citrus belt.

Figure 1 – Location and total number of trees stripped per region

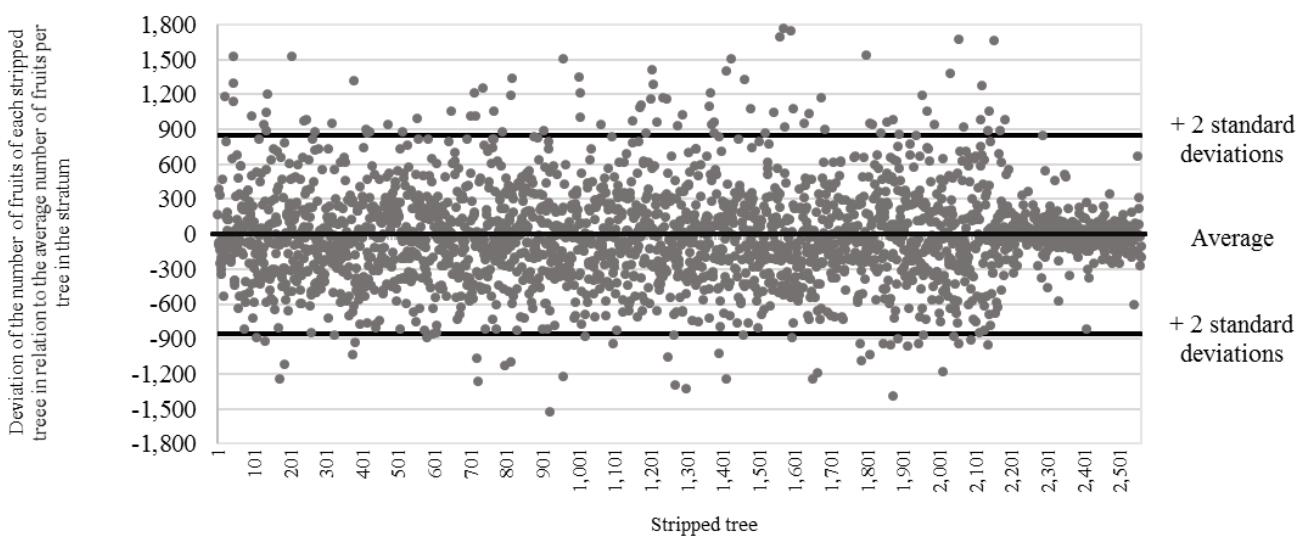

The average number of fruits per tree may vary plus or minus 17 fruits, which corresponds to 2.1% of the average number of fruits per tree obtained at stripping. This figure is within the expected error of 2% to 3% used in sizing the sample. The yield deviation distribution analysis for each stripped tree in relation to the stratum average shows that sample data is randomly distributed according to a normal distribution, as presented in Graph 5.

Graph 5 – Histogram of deviation of fruit per tree at stripping

Graph 6 shows the dispersion of deviations of each stripped tree in relation to the stratum average. It is observed that 95% of samples fall within the average \pm 2 standard deviations, that is 783 fruits.

Graph 6 – Deviation on the number of fruit at each stripping in relation to the stratum average

The tree harvested upon permit from citrus growers is indemnified at R\$ 40.00 through an online payment system where citrus growers can register and redeem the amount due.

DROP RATE – fruit drop index from tree stripping to final plot harvest

The projected average drop rate is 17.5%, distributed as follows: 10.5% for the early Hamlin, Westin and Rubi, 11.0% for other early varieties; 17.5% for the mid-season Pera Rio variety; 21.5% for the late Valencia and Valencia Folha Murcha varieties; and 22.0% for the late Natal variety. This rate is applied to the number of fruits in the tree in April 2019, when trees are stripped. The result of this calculation is the estimate of the number of fruits that will be available in the tree at harvest, since part of the oranges in the tree in the beginning of the crop season will fall throughout that period due to physiological drop, damage caused by machines, pests and diseases and adverse climatic conditions.

Should this fruit drop rate hold, it will be one of the highest rates since the first crop forecast by Fundecitrus. Major reasons for this projection are the increased greening severity and the rise in the populations of fruit borer and fruit fly during the last crop season, which then became the main cause of fruit drop, as presented in Table 1. Losses caused by these pests are expected to remain large this crop season, due to the availability of fruit in the transition between the last and the current crop. This is what likely enabled the continuity of the insect life cycle, since they could have migrated from the fruit produced from the third and fourth blooms of the previous crop, which were atypically produced in a larger proportion, to the fruit from the first and second blooms of this crop.

Other reason supporting this projection of a larger drop rate is the highly concentrated fruit production from the first and second blooms, which may result in some operational difficulties.

Table 1 – Fruit drop rates by causes from the 2015-2016 crop to the 2018-2019 crop

Causes	Drop rate			
	2015-2016 (percentage)	2016-2017 (percentage)	2017-2018 (percentage)	2018-2019 (percentage)
Physiological and mechanical.....	NA	5.99	7.45	5.16
Greening.....	NA	1.37	4.06	2.70
Fruit borer and Fruit fly.....	NA	2.34	2.70	5.70
Black spot.....	NA	3.75	2.16	2.02
Leprosis.....	NA	0.25	0.62	0.82
Canker.....	NA	0.03	0.31	0.30
Total.....	17.49	13.73	17.31	16.70

NA – Non-available data, as survey of causes for fruit drop started in the 2016-2017 crop.

Monthly and continuous monitoring by Fundecitrus as of May 2019 in 1,200 orange plots visited up to their complete harvest serves as basis to correct the rate projected at the time of this publication and consequently to correct the production estimate as well.

This year, fruit collection nets were added to 300 plots to be monitored with the aim of both obtaining a more precise drop rate and identifying fruit drop causes. Counting of fruits on branches of monitored trees in all 1,200 sample plots will also be part of the test.

FRUIT PER BOX – fruit size, that is, number of oranges to reach the weight of 40.8 kg (box) at harvest

The final fruit size projection is 260 fruits per 40.8 kg box, that is 296 fruits per box for the group of early varieties made up by Hamlin, Westin and Rubi; 270 fruits per box for the group of other early varieties; 266 fruits per box for the mid-season variety Pera Rio; 235 fruits per box for the late varieties Valencia and Valencia Folha Murcha; and 242 fruits per box for the late variety Natal.

The average size of 260 fruits per box is equivalent to oranges weighing 157 grams at harvest. The high number of fruits per tree is one of the factors that should limit the development of fruits in this crop season, due to increased competition for plant reserves, since number of fruits and fruit size at harvest are inversely proportional.

The final fruit size was estimated by a regression model that considered the final fruit size (fruits per box at harvest) as the dependent variable and the number of fruits per tree counted at stripping, the initial fruit size (fruits per box at stripping), the sum of the production from the first and second blooms in relation to the total production and the rainfall accumulated from May to July as independent variables. Data from the last eleven crops, 2008-2009 to 2018-2019, was used in the regression and is presented in Table 1. The result obtained shows an adjusted R^2 of 0.92 that means the four independent variables together explain 92% of the variation in the final fruit size (fruits per box at harvest), at a coefficient that can vary from 0 to 100%, which shows how important these variables are for the final fruit size. The comparison between the final fruit size estimated by this model and the final fruit size observed in the last eleven crops presents an average error of $\pm 2\%$.

Data relative to final fruit size (fruits per box at harvest), number of fruits per tree counted at stripping, initial fruit size (fruits per box at stripping) and the sum of the production from the first and second blooms in relation to the total production for the series from 2008-2009 to 2014-2015 was provided by orange juice companies associated to Fundecitrus – Citrosuco, Cutrale and Louis Dreyfus, which separately have estimated the production for the citrus region since 1988, with the use of objective methodology. Data was supplied individually and under a formal confidentiality agreement to an independent consulting firm for the determination of the average. Individual data supplied by each company was kept confidential. Data relative to the crops 2015-2016 to 2018-2019 comes from results of estimates performed by Fundecitrus. Data on rainfall accumulated from May to July was supplied by Somar Meteorologia.

Data used in the model to estimate the final fruit size in this crop comprises figures from the 2019 stripping and the rainfall predicted for May to July 2019 in volumes equivalent to the climatological average (1981 – 2010) calculated with information from the Climatempo website. Final fruit size estimated by the regression is 263 for the 2019-2020 crop. This size was corrected by the regression that used the observed size as the dependent variable and the estimated size as the independent variable. The size projected by this other regression is 260 fruits per box for the 2019-2020 crop.

Table 2 – Data for the 2008-2009 crop to the 2018-2019 crop and data used to estimate the final fruit size in the 2019-2020 crop

Crop	Fruits per tree at stripping	Initial fruit size at stripping	Sum of productions from first and second blooms	Accumulated rainfall from May to July	Final fruit size observed at harvest	Final fruit size estimated by the model	Error	Absolute error

Source: Fundecitrus (2015-2016 crop to 2019-2020 crop), CitrusBr (2008-2009 crop to 2014-2015 crop), Somar Meteorologia and Climatempo.

(X) Not applicable.

^e Estimated.

The result of the equation used in the crop estimate is corrected by the application of a correction factor. That is necessary because of the variables not considered in the calculations, such as harvested fruit that winds up not being used, diverse planting densities that are not included in the stratification of groves, or losses of trees throughout the crop season caused by eradication, abandonments or deaths. The correction factor of 0.10 applied in this crop is the same used since the 2017-2018 crop and represents the average of the indexes of the 2015-2016 and 2016-2017 crops estimated by Fundecitrus.

3 – TABLES OF DATA

The following tables present the 2019-2020 orange crop forecast per sector, age, bloom and variety. In tables 14 to 18, the number of fruits per tree at stripping is presented separately for the 12 regions. If the estimate were made per region, the number of stripped trees would be statistically insufficient. Hence, the maximum detail on the estimate is per sector. Still, the margin of error of the production estimate per sector is higher than the production estimate for the citrus belt as a whole.

Unexpected variations in fruit size and drop rate may change the estimate performed and will be accounted for throughout the crop by ongoing field monitoring for production estimate updates. Calculations made used whole numbers and all decimal points. Occasional divergences between figures on tables result from rounding numbers.

Table 3 – 2019-2020 Orange crop forecast by sector

Sector	Mature groves area	Average density ¹ of mature groves	Bearing trees	Fruit per tree at stripping ²	2019-2020 Orange crop forecast		
					Per tree	Per hectare	Total
	(hectares)	(trees/hectare)	(1,000 trees)	(number)	(boxes/tree)	(boxes/hectare)	(1,000,000 boxes)

ANNEX: DIFFERENCES BETWEEN PUBLISHED VERSIONS

The following chart presents improvement resulting from text review and information included to meet demands from the citrus segment and the press. Slight text and formatting adjustments that do not change the meaning of the text are not shown on the chart.

Chart 4 – Differences between published versions

Section	Page in the version Nº 1	Page in the version Nº 2	Page in the version Nº 3	Change
I	26	26	26	Included in the 3 rd paragraph: "...in addition to being affected by the water deficit and higher temperatures resulting in lower yield..."
I	31,32,33	31,32,33	31,32,33	In Tables 6, 10 and 13 the eradication period was included as being "April 2018 to March 2019".
I	40	41	41	Table 25 and subsequent ones were moved to the following page.
I	96	96	96	In Table 96 the planting holes subtotal for the region of Limeira was included.
I	-	-	-	Footnote "- Represents zero" was excluded in all tables.
